Introduction

This notebook performs an analysis of use of optimization related packages and methodologies for all R packages available on CRAN.

Two methods are used and results are compared.

Method 1: Grep for non-empty src directories. By convention, packages using compiled code (C, C++, Fortran) place files in the '/src' directory.

Method 2: Check for stated dependencies on packages.

Potential problems/limitations:

The best evidence of optimization would be in history of commits and unit test runs. While all packages have source code available, not all have development history available nor unit tests available.

Use of one of these specified packages doensn't mean user is trying to optimize. Package dependencies can be misleading - I've seen CRAN packages that list packages as dependencies and by inspection of their source code, they never use it.

Grepping for non-empty src directory

liquidSVM is a good example of an optimized and tested package - see https://arxiv.org/pdf/1702.06899.pdf * has no optimization related dependencies (so wont show up in depedency based section) * core of package implemented in C++

Iso package has Fortran code that pre-dates 2013/* Does it use Fortran code for performance reasons, ease of implementation, legacy reasons, or ???

From manual review, it seems that all C++ and Fortran code is in src directory. External/third party libraries are usually included in other directories.

One potential problem is use of Java - while it seems that due to how rJava allows Java code to be called from R, a memory perfomance hit may occur - but some specific packages do mention that using Java threading improves performance - see package 'rmcfs' as an example

At this point, just look for non empty src directory...

```
# if value 100%, then read all packages, otherwise, randomly select number of packages provided
sample_size <- '100%'
# dont need to untar, but is useful for manual analysis
untar_files <- FALSE

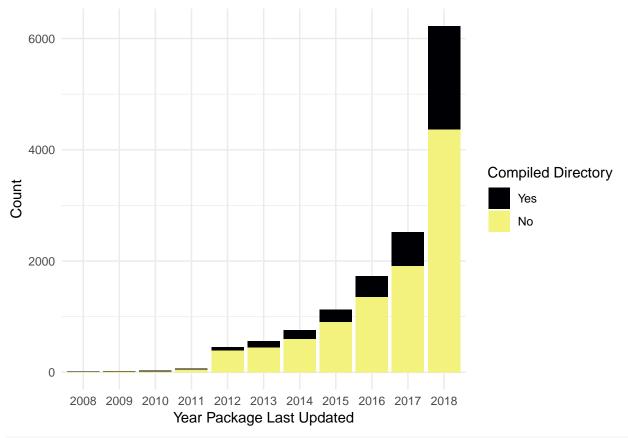

# call code from shared_fn.R to download files and extract them if desired
package_df <- initialize(search_pattern="src[^/]*/.+", sample_size=sample_size, untar_files=untar_files

if (nrow(package_df[package_df$download_error == TRUE, ]) > 0) {
    print('Unable to download or untar these packages - they will not be considered in analysis')
    print(package_df[package_df$download_error == TRUE, ])
} else {
    print('It appears that all files downloaded and untared successfully.')
}

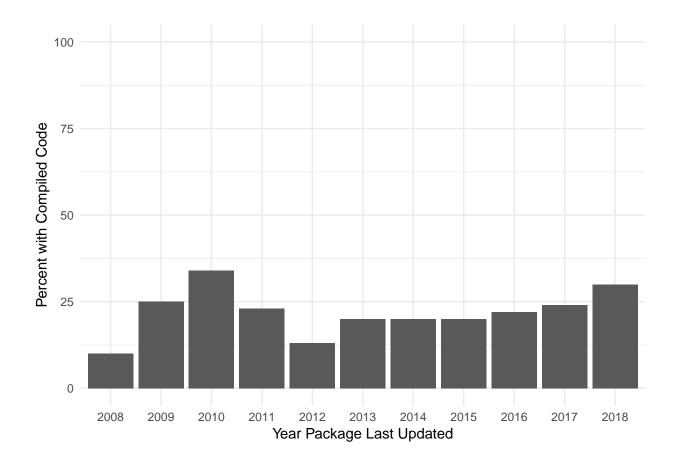

print(paste('As of', date(), 'there are', nrow(package_df), 'packages available on CRAN'))
```

Visualizations and Tables for Grep results

```
# build data needed for plots
gtf <- grep_table_freqs(package_df)</pre>
gtt <- grep_table_totals(gtf)</pre>

## DSL
```

Method comparison

As the results from method 1 do not match the results from method 2, explore some of the differences.

Some points discovered: * It is possible to list a one of the sought for packages as a dependency and not acutally use the package * Speculation - Optimization can occur in many ways. Some well known items are (at the time of this writing) are to prefer matrices over data.frame or to avoid using data.frames with the apply family of functions. It's impossible to determine for all packages what process the developer went through and what options were considered when arriving at the currently available package version.

As new packages are being released and updated all the time, these numbers will change.

```
# About 846 more appear to use compiled code
print("Difference between packages that have src directory vs dependency on optimization framework:")

## [1] "Difference between packages that have src directory vs dependency on optimization framework:"

nrow(package_df[package_df$found == TRUE, ]) - nrow(package_df[package_df$package_deps != 'none', ])

## [1] 818
